Introducing JPAD - Java Programs for Aircraft Design

- A software toolchain for aircraft preliminary design and MDO
- A modern, user friendly, modular framework.
- Support for simultaneous management/analysis of several aircraft and/or 'varied' configurations of the same aircraft.
- Conceived for collaborative design activities.
- Interoperability with other tools/disciplines (CAD/CFD/FEM analysis).

Main features

- Define a **parametric representations of a complete aircraft** with XML configuration/input files.
- Generate **CAD geometries** of aircraft assembly and sub-components. Measure lengths, areas, volumes.
- Perform various types of analysis (L0, L0.5, L1): **Aerodynamics, Stability & Control, Performance, Weight & Balance, Costs.**
- Exports analysis results in **XML** and **Excel formats**. Produce useful **output charts** for each analysis.
- Perform iterative analysis in order to reach an optimum configuration. (**Work in progress**)

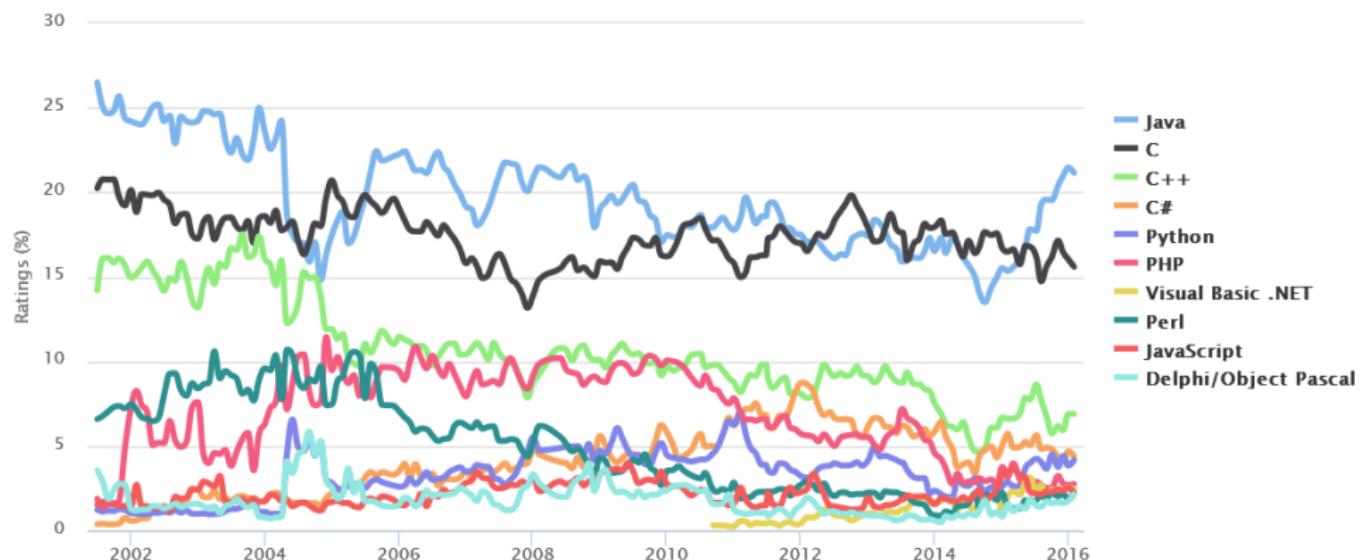

Java. Why?

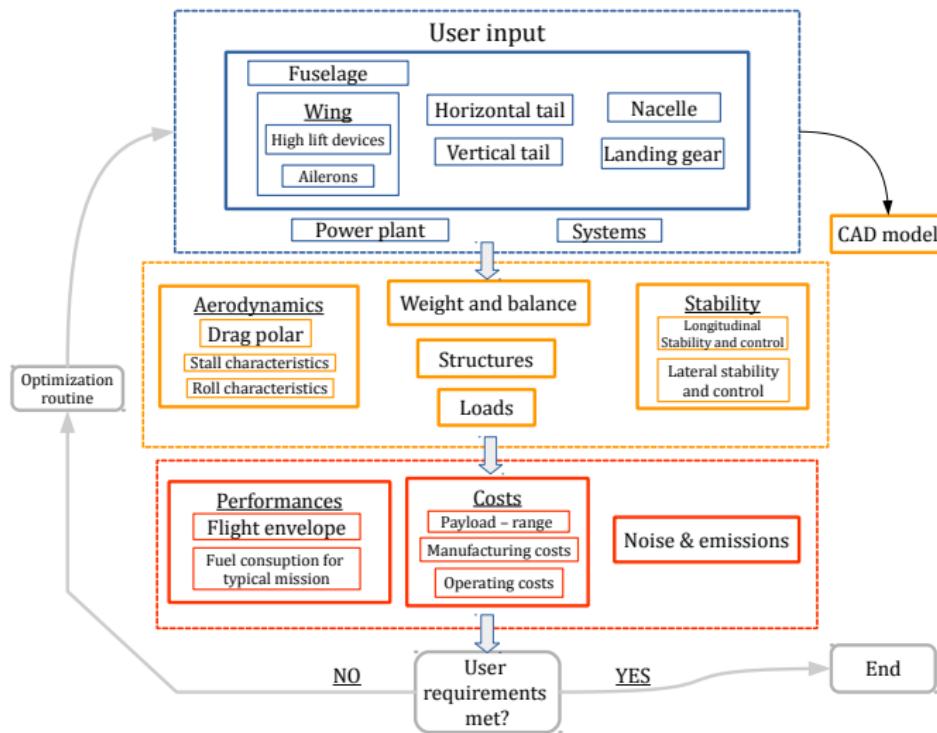

- **Language widely supported.** This avoids the library to become obsolete due to the aging of the programming language used.
- The language promote the use of **open source libraries**, especially for I/O tasks and for complex mathematical operations.
- **Widely supported GUI frameworks** (SWT/JFace and JavaFX) and a GUI visual builders.
- **Object-Oriented paradigm** is naturally applied in the abstraction of typical Aircraft Design problems.
- Promotes **modularity**: easier to work with in an ever changing team.

TIOBE Programming Community Index

JPAD typical work session

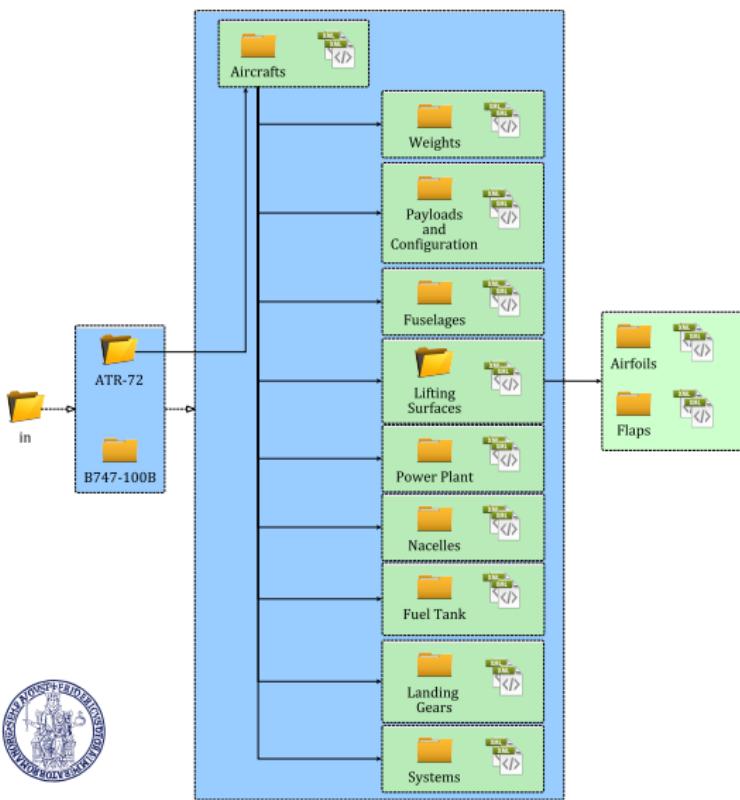

Input file

The input file type chosen is the **XML** (*eXtensible Markup Language*). It is a markup language that defines a set of rules for encoding documents in a format which is both *human-readable* and *machine-readable*; moreover its design goals of emphasize simplicity, generality and usability across the Internet.

- *Markup Language* due to the use of tags that describes the content.
- *extensible* because the markup symbols are unlimited and self-defining, so that it is possible to use a personal tag for each data.

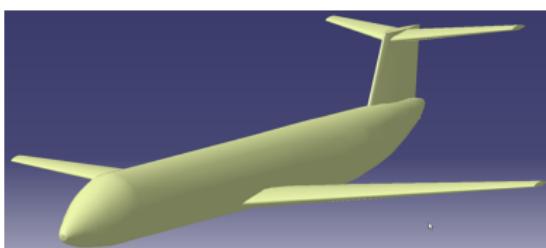

Input file structure prototype

```
<?xml version="1.0" encoding="utf-8"?>
<jpad_config>
  <aircraft>
    <wings>
      <wing type="WING" file="wing.xml">
        <position>
          <x unit="m">12.0</x>
          <y unit="m"> 0.0</y>
          <z unit="m"> 2.0</z>
        </position>
        <rigging_angle unit="deg">2.0</rigging_angle>
      </wing>
    </wings>
    <fuselages>
      <fuselage file="fuselage.xml">
        <position>
          <x unit="m">0.0</x>
          <y unit="m">0.0</y>
          <z unit="m">0.0</z>
        </position>
      </fuselage>
    </fuselages>
  </aircraft>
</jpad_config>
```

ADOpT GUI

- **Menu bar**, holds all the available actions.
- **Toolbar**, holds the actions needed to interact with the application.
- **Project tree**, provides access to all the aircraft components and the analysis results any time.
- **3D view**, shows the CAD model which can be updated each time.
- **Log message window**, tells the status of pending operations.
- **Tab folder**, contains all the windows opened.

Specific Range and Cruise Grid chart

- **Cruise grid chart** is a very important tool for pilots because it allows to choose the correct speed, during the cruise phase, in order to follow some mission objectives like minimum fuel consumption or a fast cruise.
- In **Breguet equations** the focus is on the **autonomy factor A.F.**

Autonomy Factor Propeller

$$A.F. = \left(\frac{\eta_p}{SFC} \right) \left(\frac{L}{D} \right)$$

Autonomy Factor Jet

$$A.F. = \left(\frac{V}{SFCJ} \right) \left(\frac{L}{D} \right)$$

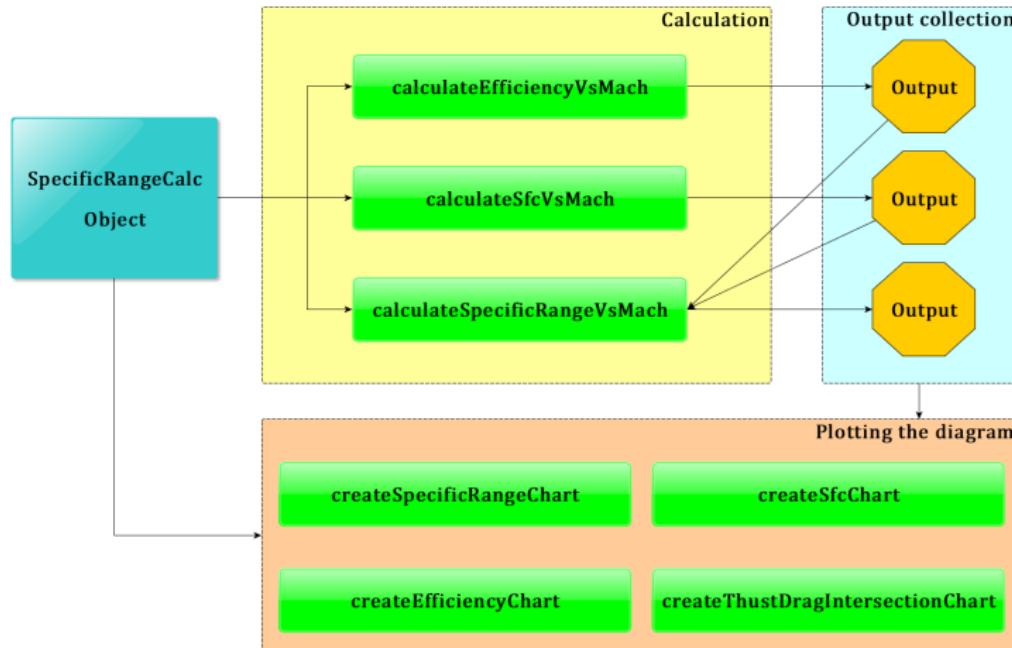

DIPARTIMENTO DI
INGEGNERIA
INDUSTRIALE

Specific Range calculation

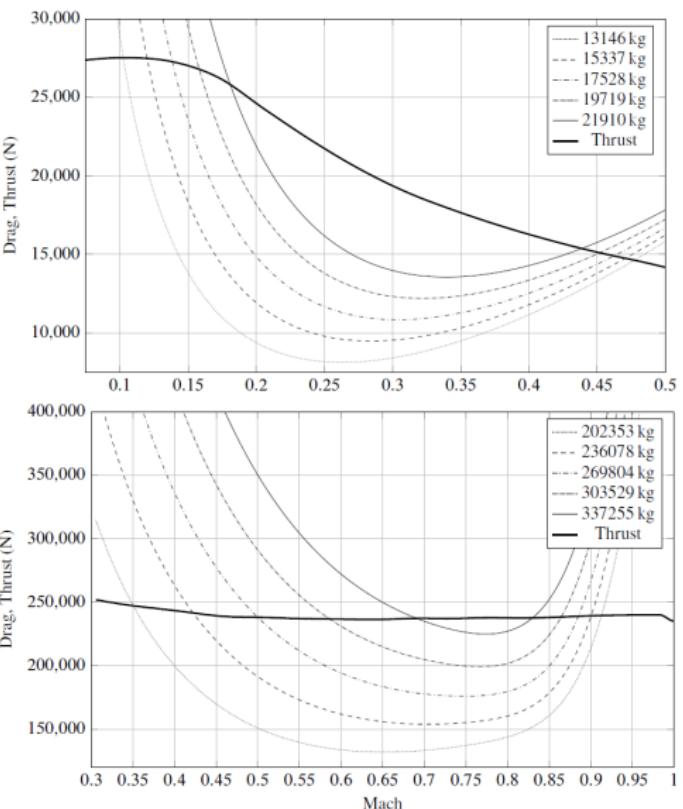

- From the aircraft weight in cruise condition the C_L can be calculated.
- With this C_L the related C_D can be calculated taking into account the wave drag, if present.
- From engine database the SFC can be easily calculated in the given flight condition.
- At a given speed, or with known propeller efficiency, the A.F. can be calculated.
- The specific range can be calculated from the A.F. dividing it by the aircraft weight in cruise.
- This can be done for several Mach numbers, between the maximum and minimum one from the flight envelope at that altitude, and several aircraft weights.

Trailing-edge devices effects

- Higher C_L at a given angle of attack and higher $C_{L\max}$.
- Lower stalling angle of attack.
- Lower zero-lift angle due to increasing camber.

Leading-edge devices effects

- Extension of the linear trait of the lift curve with an increase of the stalling angle of attack and of the $C_{L\max}$
- Higher zero-lift angle caused by leading edge deflection which reduce the actual angle of attack.
- Higher slope of the linear trait of the lift curve.

Calculation methodologies

- Charts, semi-empirical equations and experimental data have been used to evaluate high lift devices effects. (e.g.: *Glauert's linearized theory for thin airfoils with flaps*, DATCOM, Young and Hufton experimental data)
- Effects to evaluate:
 - ΔC_{l0} , ΔC_{L0}
 - $\Delta C_{l\max}$, $\Delta C_{L\max}$
 - $C_{L\alpha,\text{flap}}$
 - $\Delta\alpha_{\text{stall,airfoil}}$, $\Delta\alpha_{\text{stall,wing}}$
 - ΔC_{D0}
 - $\Delta C_M, c/4$

ODE set for the AOE take-off distance calculation

State space representation $\dot{\vec{x}} = \vec{f}(\vec{x}; u)$

$$\begin{Bmatrix} \dot{s} \\ \dot{V} \\ \dot{\gamma} \\ \dot{h} \end{Bmatrix} = \begin{Bmatrix} f_1(s, V, \gamma, h; \alpha) \\ f_2(s, V, \gamma, h; \alpha) \\ f_3(s, V, \gamma, h; \alpha) \\ f_4(s, V, \gamma, h; \alpha) \end{Bmatrix} \quad \text{with} \quad \begin{Bmatrix} x_1 = s \\ x_2 = V \\ x_3 = \gamma \\ x_4 = h \end{Bmatrix} \quad \text{and} \quad u = \alpha$$

- $f_1(\vec{x}, u) = x_2$
- $f_2(\vec{x}, u) = \frac{g}{W} \begin{cases} T(x_2) - D(x_2, u) - \mu[W - L(x_2, u)] & \text{if } S(x_2, u) < 1 \\ T(x_2) \cos u - D(x_2, u) - W \sin x_3 & \text{if } S(x_2, u) \geq 1 \end{cases}$
- $f_3(\vec{x}, u) = \frac{g}{W x_2} \begin{cases} 0 & \text{if } S(x_2, u) < 1 \\ L(x_2, u) + T(x_2) \sin u - W \cos x_3 & \text{if } S(x_2, u) \geq 1 \end{cases}$
- $f_4(\vec{x}, u) = x_2 \sin x_3$

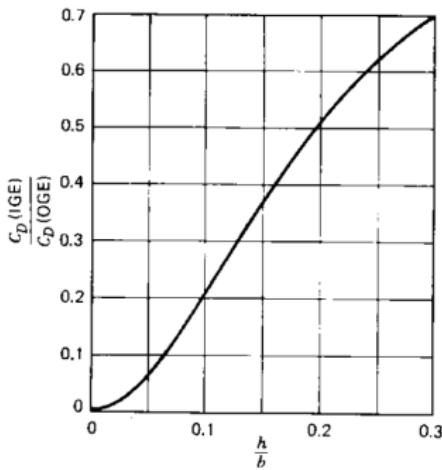

$$S(x_2, u) = \frac{L(x_2, u)}{W \cos x_3}$$

ODE set for the AOE take-off distance calculation

State vector and input $\vec{x} = \{x_1 = s; x_2 = V; x_3 = \gamma; x_4 = h\}; u = \alpha$

- $T(x_2)$ is read from the engine database related to the take-off setting.
- $D(x_2, u) = \frac{1}{2} \rho (x_2 + V_w \cos x_3)^2 S C_D(u)$
 - $C_D(u) = C_{D0} + (\Delta C_{D0})_{flap+lg} + K_g \frac{C_L^2}{\pi A Re}$
 - $K_g = -622.44x^5 + 624.46x^4 - 255.24x^3 + 47.105x^2 - 0.6378x + 0.0055$
- $L(x_2, u) = \frac{1}{2} \rho (x_2 + V_w \cos x_3)^2 S C_L(u)$
 - $C_L(u)$ is the one from the lift curve with flaps, and eventually slats, deflected.

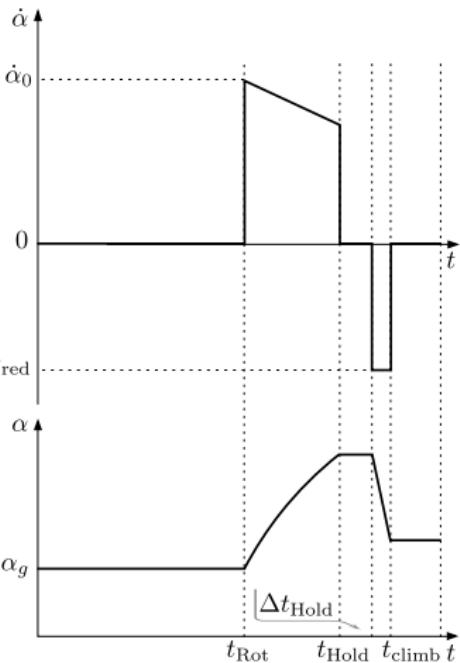

ODE set for the AOE take-off distance calculation

$$u(t) = \begin{cases} \alpha_g & \text{if } t < t_{\text{Rot}} \\ \alpha_1(t) & \text{if } t \geq t_{\text{Rot}} \end{cases}$$

$$\alpha_1(t) = \dot{\alpha}(t) dt$$

$$\dot{\alpha}(t) = \begin{cases} \dot{\alpha}_0 (1 - k_\alpha \alpha) & \text{if } t_{\text{Rot}} \leq t < t_{\text{Hold}} \\ 0 & \text{if } t_{\text{Hold}} \leq t < t_{\text{Hold}} + \Delta t_{\text{Hold}} \\ \dot{\alpha}_{\text{red}} & \text{if } t_{\text{Hold}} + \Delta t_{\text{Hold}} \leq t < t_{\text{climb}} \\ 0 & \text{if } t \geq t_{\text{climb}} \end{cases}$$

ODE set modification for the take-off in OEI condition

OEI continued take-off

- There is a discontinuity in thrust at a specific failure speed V_{ef} .
- $T(x_2)$ is still read from the database but considering a number of engines reduced by one from the time t_{ef} at which the engine failure occurs.

OEI aborted take-off

- The take-off run, up to the engine failure speed V_{ef} , is the same as the continued take-off one.
- The pilot reacts at a time t_{act} (generally 3 s after t_{ef}) setting $T(x_2)$ to 0 and activating brakes. The equation f_2 changes in the following.

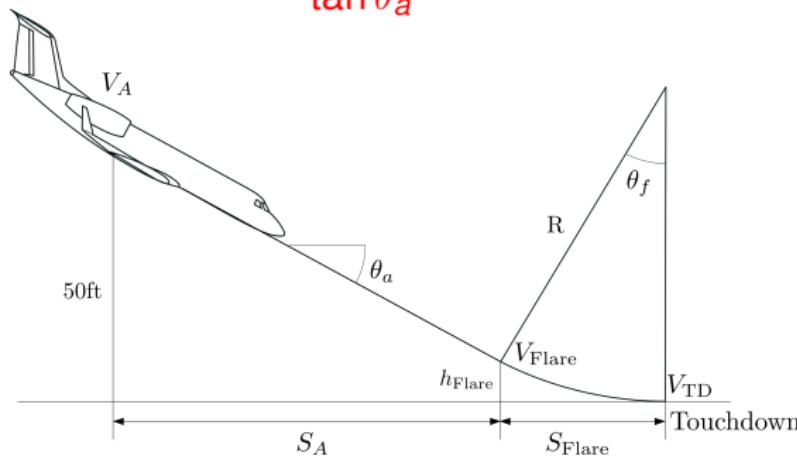

$$f_2(\vec{x}, u) = \frac{g}{W} \left\{ -D(x_2, u) - \mu_{brakes} [W - L(x_2, u)] \right\}$$

Landing distance calculation

Air run

- $[n = 1.2, V_{\text{Flare}} = 1.23 V_s] \rightarrow R = \frac{V^2}{g(n-1)} = \frac{V_{\text{Flare}}^2}{0.2 g}$
- $[\theta_a \approx 2^\circ \div 3^\circ] \rightarrow h_{\text{Flare}} = R(1 - \cos \theta_a)$
- $[\theta_a, R, h_{\text{Flare}}] \rightarrow S_A = \frac{50 - h_{\text{Flare}}}{\tan \theta_a}; \quad S_{\text{Flare}} = R \sin \theta_a$

Landing distance calculation

Ground run

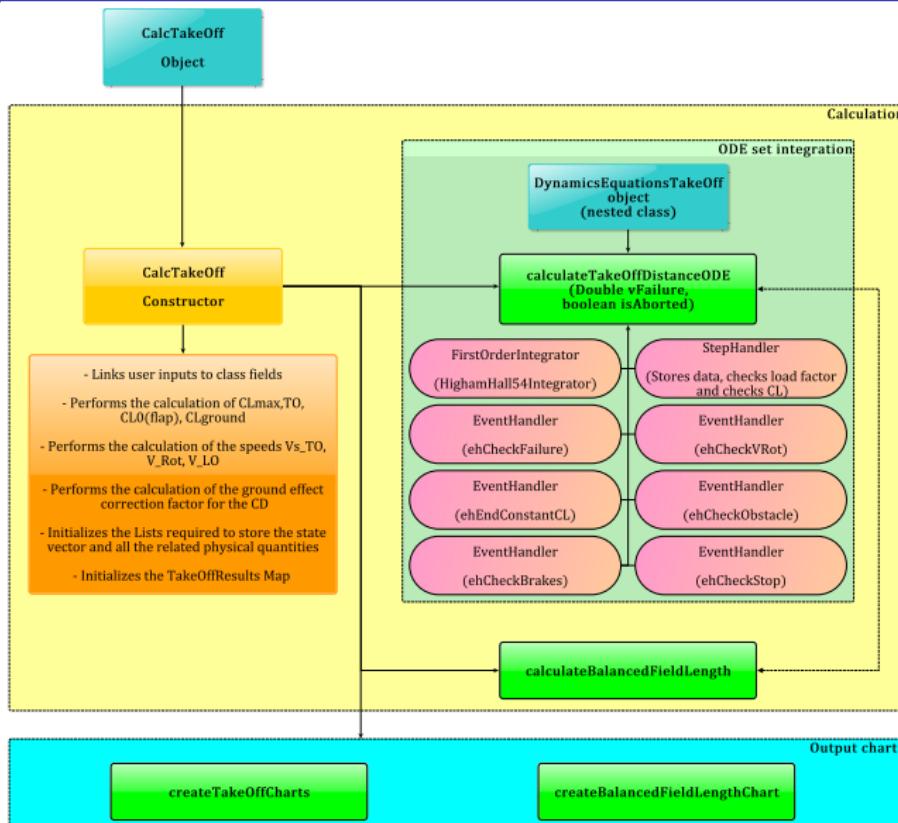

$$\begin{Bmatrix} \dot{s} \\ \dot{V} \end{Bmatrix} = \begin{Bmatrix} f_1(s, V) \\ f_2(s, V) \end{Bmatrix} \quad \text{with} \quad \begin{Bmatrix} x_1 = s \\ x_2 = V \end{Bmatrix}$$

- $f_1(\vec{x}, u) = x_2$
- $f_2(\vec{x}) = \frac{g}{W} \begin{cases} -T_{\text{Rev}}(x_2) - D(x_2) - \mu[W - L(x_2)] & \text{if } t \leq t_{\text{fr}} \\ -T_{\text{Rev}}(x_2) - D(x_2) - \mu_{\text{brakes}}[W - L(x_2)] & \text{if } t > t_{\text{fr}} \end{cases}$

t_{fr} is related to the end of the *free-roll distance* (which represents the distance covered while the pilot reduces the power to idle, retracts the flaps, deploys the spoilers, and applies the brakes) and it's set at 3 s.
